ABSTRACT

Infrastructure-as-Code (IaC) is a technology that enables the management and distribution of infrastructure through code instead of manual processes. In 2020, Palo Alto Network’s Unit 42 announced the discovery of over 199K vulnerable IaC templates through their “Cloud Threat” Report. This report highlights the importance of tools to prevent vulnerabilities from reaching production. Unfortunately, we observed through a comprehensive study that a security linter for IaC scripts is not reliable yet—high false positive rates. Our approach to tackling this problem was to leverage community expertise to improve the precision of this tool. More precisely, we interviewed professional developers to collect their feedback on the root causes of imprecision of the state-of-the-art security linter for Puppet. From that feedback, we developed a linter adjusting 7 rules of an existing linter ruleset and adding 3 new rules. We conducted a new study with 131 practitioners, which helped us improve the tool’s precision significantly and achieve a final precision of 83%. An important takeaway from this paper is that obtaining professional feedback is fundamental to improving the rules’ precision and extending the rulesets, which is critical for the usefulness and adoption of lightweight tools, such as IaC security linters.

CCS CONCEPTS

• Security and privacy → Vulnerability scanners.

Security, Infrastructure, Linter

ACM Reference Format:

1 INTRODUCTION

Software configuration management and deployment tools like Puppet1, Ansible2, and Chef3 became popular amongst software development warehouses [18, 29]. The adoption of these tools has increased with the growing movement to run software in cloud servers. These tools help infrastructure teams increase productivity by automating various configuration tasks (e.g., server setup). In short, these tools describe the environment configuration in a set of provisioning scripts that can be versioned and reused. They enable configuration consistency between different environments and can reduce the time required to provision and scale the infrastructure. The process of managing and provisioning infrastructure through configuration scripts is called Infrastructure-as-Code (IaC). IaC tools take a script as input and create an infrastructure that typically runs in a virtual environment as output. As with any piece of code, IaC scripts are also prone to defects such as security vulnerabilities [28]. For example, in 2020, Palo Alto Network researchers reported the discovery of over 199K vulnerable IaC templates [1]. Specifically, 42% of AWS CloudFormation templates, 22% of Terraform templates, and 9% of Google Kubernetes YAML files were vulnerable. In addition, researchers found more than 67k potential security smells in IaC scripts implemented in Ansible, Chef, and Puppet [32] through an ad-hoc tool created to show the presence of a new set of anti-patterns for security in the IaC domain. These reports highlight the importance of tools to prevent vulnerabilities from reaching production and shift security left in the development pipeline.

Figure 1 shows an example of an Admin by default weakness (CWE-2504), a potential vulnerability in a Puppet manifest in a module of the PuppetLabs.5 The vulnerability manifests when the developer configures a user as “admin” or “root” for an infrastructure component. In this example, the $grafana_user is set as “admin” for the different services (Puppetserver, Puppetdb, PostgreSQL, Filesync) used by Grafana6. Therefore, any service can be prone to a privilege escalation attack. In IaC, all the infrastructure

6Grafana is an open-source software application for data exploration and visualization. More information available at https://grafana.com/
components are configured through scripts, including the access credentials. Specifying default users as administrative gives privileges to users that only an administrator should have. Admin accounts can be exploited to access sensitive data and execute unauthorized code/commands. Infrastructure engineers should avoid setting admin passwords and usernames to user accounts that do not need the privileges. Detecting these issues automatically essential to make infrastructure engineers aware of possible security problems and to help companies build more robust infrastructures.

Problem: Puppet IaC Security Linters are not reliable yet! In 2019, Rahman et al. showed that IaC scripts—just like any piece of code—are not immune to security vulnerabilities [28, 30]. They focused on Puppet configuration files and listed seven anti-patterns that could lead to security vulnerabilities. The work led to the development of SLIC, a linter to detect those defects in Puppet scripts. Linters are often imprecise tools [4, 8, 12, 19, 22, 34]. Therefore, motivated by the report of very high accuracy (i.e., precision and recall) from their paper (Table IV [28]), we decided to conduct a reproduction study of SLIC based on a different and larger set of projects. We asked students (co-authors of this paper) and developers to analyze the warnings that the tool reports. To validate the students observations of low precision, we reported a sample of the warnings of the tool to maintainers of 86 open-source projects. From the 228 issues created, we obtained responses to 51 issues where only 33 issues were discussed or clear. Results showed that the tool performs differently in a new set of projects, particularly when validated by the software owners. The precision observed was smaller than the one reported in SLIC’s original paper (28% instead of 99%) which indicates that security IaC linters for Puppet are not reliable yet due to the high false positive rates.

Like many linters, SLIC uses simple rules to detect issues. Essentially, it searches for string patterns in the values of tokens (many times) regardless of their type (e.g., variable, string, etc.) and the relationship between them. For instance, the “Usage of Crypto Algorithms” checker (CWE-326\(^7\)) searches for any token whose value includes sha1 or md5. Both are built-in Puppet functions and SLIC fails to consider the context of usage of these algorithms, i.e., these functions are called in Puppet manifests to encrypt data (e.g., encrypt_key = md5(key)). Therefore, SLIC incorrectly detects md5checksum = ‘07bd73571b7828b73f4c8ed9bc5526d’ as a CWE-326, which is an anti-pattern. This simplicity creates much noise for developers. In this preliminary study, we observed that the rules for the current IaC security anti-patterns must be better designed to be safely adopted by the industry and avoid productivity disruption.

Solution: Our preliminary study revealed that (1) there is a need to improve the precision of IaC security linters for Puppet, and that (2) security tools can be iteratively improved and extended by incorporating feedback from the developer community as suggested in previous work [34]. This paper reports on the process we followed to iteratively and incrementally improve the precision of an IaC linter according to user feedback. For example, the experiments described above ignited discussions with members of the development and security teams of PuppetLabs\(^8\), as well as one project manager from Vox Pupuli\(^9\). The feedback collected from the team, OSS maintainers and the Puppet community led to the creation of a new tool, which we dubbed INFRASECURE. Later, we leveraged the expertise of practitioners experienced in IaC tools or security to iteratively and incrementally improve the new tool.

Figure 2 shows the timeline of feedback collection followed to design and improve INFRASECURE. To sum up, we bootstrapped the design of INFRASECURE with rules obtained from the revision of SLIC’s ruleset, according to the feedback of the research team and owners of OSS projects (phase 1 in Figure 2); and, incrementally evolved the linter according to the recommendations of practitioners (phase 2 in Figure 2). We improved 7 rules of the SLIC ruleset and added 3 new rules that were either recommended by practitioners (e.g., weak password); or relevant for the infrastructure domain (e.g., homograph attacks\(^10\)) and malicious dependencies.

Main Results: This paper performs the following contributions:

- **Study.** A replication study of SLIC’s precision, including a preliminary study conducted with two researchers (co-authors of this paper) and a study with several GitHub scripts validated by project maintainers;
- **InfraSecure.** A new linter adjusting 7 rules of the original SLIC ruleset and adding 3 new rules with a final precision of 83%.
- **Dataset.** A dataset of IaC scripts with more than 1000 warnings classified as false positives and true positives that researchers can use to evaluate other security linters;

*Take-away message:* The takeaway message of this paper is that it is feasible to tune security linters to produce acceptable precision for important classes of warnings (confirming the findings reported in a study at Google [34]) and that involving practitioners in discussions is an effective way to guide the improvement of those linters.

**Replication Package:** All the scripts and data used in this study (including feedback obtained from the maintainers and practitioners) are available at: https://figshare.com/s/6b6a769b13933ae0774c

2 **BACKGROUND**

This section provides background information on Puppet and discusses security weaknesses in IaC scripts.

#### 2.1 Puppet

Developers no longer deal with systems composed of a single machine and database. Instead, system administrators must manage multiple diverse operating systems, databases, and virtual machines. Perhaps most importantly, they must ensure their configurations are consistent at any given time. Configuration management technologies have been around for over a decade—Puppet was founded in 2005. Puppet is a solution that helps IT infrastructure management through code by supporting software deployment, packages, and configuration. In Puppet, programs are written using Puppet’s declarative language. They are called manifests. More information about the language can be found elsewhere.

#### 2.2 Security Weaknesses

This section describes in more detail the potential weaknesses in Puppet scripts. Table 1 illustrates examples of each weakness.

**Hard-coded secrets (CWE-798):** This warning refers to the practice of including sensitive information such as passwords or cryptographic keys in code files. Table 1 shows a hard-coded password example. Rahman et al. considered 3 kinds of data as sensitive: usernames, passwords, and cryptographic keys. However, the Common Weakness Enumeration list does not consider solo hard-coded usernames as a threat. Practitioners involved in our validation studies shared the same opinion. Therefore, we argue that hard-coded usernames should be only reported when there is a paired password (CWE-259) or cryptographic key (CWE-321).

More discussion on this is provided later in Section 4.2.

**Use of HTTP without TLS (CWE-319):** This warning refers to the practice of using HTTP without the Transport Layer Security (TLS) to transmit sensitive data. This means that attackers can more efficiently exploit the communication channel as the data is transmitted uncrypted, as cleartext.

---

**Suspicious comment (CWE-546):** This warning refers to comments that suggest the presence of bugs, missing security functionalities, or weaknesses of a system. Details provided in comments about bugs, security functionalities or weaknesses can be crucial for hackers to exploit the infrastructure.

**Use of weak cryptography algorithms (CWE-326):** This warning refers to using weak crypto algorithms. Attackers can easily crack the encryption schemes and have access to the data.

**Invalid IP address binding (CWE-284):** This warning refers to assigning the address 0.0.0.0 to a server. This practice allows connections from any IP address to access that server. While mail servers have to listen on 0.0.0.0 to receive mail, database servers should not since it can lead to critical data breaches.

**Empty password (CWE-258):** This warning refers to using empty strings as passwords, which are easily guessable.

**Admin by default (CWE-250):** As detailed in the Introduction, this warning refers to defining users with administrative privileges. This can result in security weaknesses since it can disable or bypass security checks performed by the system.

**Weak Password (CWE-521):** This warning refers to the usage of weak passwords. Weak passwords are easily guessable and can be bypassed to gain access to systems.

**Insufficient Visual Distinction of Homoglyphs Presented to User (CWE-1007):** This warning refers to malicious actors using homoglyphs that may cause the user to misinterpret a glyph and perform an unintended, insecure action. The homograph attack performed against the apple website is a well-known example of this type of weakness. Table 1 shows an example of a domain where the character  " could be replaced by the respective homoglyph, as in the apple attack. This warning might be essential to uncover malicious domains implanted by malicious open-source contributors—typosquatting attacks.

**Malicious Dependencies (CWE-829):** This warning refers to malicious software by nature, i.e., dependencies that integrate known vulnerabilities (CVEs). These are the leading cause of supply chain attacks, and one of the main challenges the security community faces nowadays.

3 **PRELIMINARY STUDY**

This section reports on the findings of two studies—involving different sets of participants—to assess the performance of SLIC, a recently-developed linter for Puppet.

#### 3.1 Validation with Students

This section reports on a study involving two of this paper’s authors to assess the precision of SLIC on an independent benchmark. The study consisted in inspecting 502 warnings reported by the tool. The warnings were validated by one senior PhD student whose research focuses on security and static analysis and one junior PhD student in software engineering with basic security skills.

---

[15] CWE-798 description is available at [https://cwe.mitre.org/data/definitions/798.html](https://cwe.mitre.org/data/definitions/798.html)

[16] This kind of issues can lead to man in the middle (MITM) attacks: [https://owasp.org/www-community/attacks/Man-in-the-middle_attack](https://owasp.org/www-community/attacks/Man-in-the-middle_attack)

were discussed to reach a consensus. We report on the results of a Cohen’s Kappa analysis [10] to measure the inter-rater reliability by two co-authors. Cases where the authors found disagreement was reached were updated with the final conclusion—inferred from the discussion between both co-authors.

### Results

#### Dataset

To build our dataset, we mined GitHub projects containing Puppet scripts. We used three different queries to search for repositories: 1) language:puppet is:public; 2) puppet in:readme is:public; and, 3) devops is:public. We discarded results pointing to forked repositories (to avoid duplicates) and discarded results pointing to repositories without any code in Puppet scripts. Our crawler found a total of 1419 GitHub repositories and 34574 associated Puppet scripts. SLIC scanned these scripts for the seven sins and reported a total of 31990 security warnings involving 9144 Puppet scripts (26.5% of the total) from 1093 repositories (73.5% of the total). Table 2 shows the breakdown of warnings reported by SLIC. Column “Rule” shows the name (kind) of the warning, column “#” shows the number of warning reports of that kind, and column “%” shows the percentage of the total associated with that number. This table lists the warnings in order of their prevalence.

### Methodology

#### Samples

Given the high number of warnings reported by the tool (31990) and the need for humans to analyze each warning, we sampled a set of reported warnings. We leveraged two popular complementary sampling strategies to that end [5]. Stratified sampling is a method to draw samples from a set by taking into account the distribution of kinds—in our case, the distribution of kinds of warnings. A proportional (stratified) sampler draws samples in a number proportional to the size of the sets associated with each kind whereas an uniform (stratified) sampler draws the same number of samples for each kind. Intuitively, a proportional sampler values more the most prevalent kinds of warnings (as to make more accurate measurements on those kinds) whereas an uniform sampler treats every kind equally (as to avoid inaccurate measurements on uncommon kinds). We sampled 250 warnings proportionally and 252 (=36*7) warnings uniformly. In total, we analyzed 502 warnings, which is a substantial increase when compared to the 58 warnings analyzed in the SLIC’s paper [30]. Metric. We focused on precision to measure the reliability of the reports of the tool. Precision is especially important for security linters. Reporting scores of false warnings can be highly disruptive for a team’s productivity, as team members tend to interrupt work to address high-priority tasks [13]. Developers are less willing to use linters with low rates of precision because they find them not trustworthy and unreliable [34]. Statistical Tests. Each one of the 502 warnings was manually inspected by two co-authors. Cases where the authors found disagreement were discussed to reach a consensus. We report on the results of a Cohen’s Kappa analysis [10] to measure the inter-rater reliability of human decisions.

### Validation with Owners of OSS Projects

Complementing the preliminary study reported in the previous section, this section reports on the findings of a validation study of SLIC conducted with the maintainers of open source projects. The motivation of this study was to confirm the observations of the previous experiment but now with open source developers, i.e., developers with more context of the software under analysis. GitHub issues were designed to illustrate the security smells (including references to the corresponding CWEs15) and to guide the developer towards patching the issue. We followed guidelines for issue reporting from the literature. Issues include code samples, links to more information and we strive to make the report message

---

as brief and objective [6]. Figure 3 shows an example of an issue created for a "Hard-coded Secret". The title is "Potential vulnerability in Puppet file: Hard-coded Secret". The issue (1) shows where the potential vulnerability is (code: `cron_user = 'root`, script: `puppet-apt_mirror/manifests/init.pp` line: 191); (2) explains the vulnerability and its possible implications (bypass protection mechanism, gain privileges on applications, and access to sensitive data); and (3) makes a recommendation to the developer on how she can fix the vulnerability (by using a vault, in this case). We created different templates of this message for the different warning types.

3.2.1 Dataset. The dataset used in this study was different from the one from Section 3.1.2. We mined GitHub projects with activity in 2020 (at least one commit) and containing Puppet scripts. We conjectured that focusing on projects with recent activity would increase our chances of obtaining responses. We used two different queries to search for repositories: 1) language: puppet is:public and, 2) puppet in: readme is:public. We discarded results pointing to forked repositories (to avoid duplicates), repositories without any activity in 2020 (no commits), and repositories without any code in Puppet per project. Our tool scanned 3740 Puppet scripts from 287 GitHub repositories. In total, 1975 security warnings were detected in 1147 Puppet scripts (=30.7% of the total). We issued alerts to projects with maintainers involved in the slack of the Puppet community. We received 51 answers to the 228 issues we submitted, but only 33 issues were clearly validated by practitioners—which were the ones we considered for our conclusions.

3.2.2 Methodology. This section presents the methodology followed to submit the issues. Sample. A total of 287 GitHub repositories were scanned to this study. We ensured that the repositories had recent activity (at least one commit in 2020) to improve the probability of obtaining responses. The total amount of scripts scanned was 3740 – 7 times the sample used in our preliminary study (Section 3.1.1) and 28 times the sample used in Rahman et. al [28] to evaluate the SLIC’s precision and recall. Issues. We reached out to the software owners through the Puppet community slack and submitted issues to projects with maintainers involved in the slack community. All the issues followed a specific template depending on the type of warning (cf. Figure 3). The issued message not only located and explained the vulnerability but also recommended an example of a patch (i.e., actionable messages to save maintainers time). Reply Evaluation. We monitored the discussion threads associated with the issues. For each response obtained, we classified the warnings reported as true positives (TP) or false positives (FP) according to the opinion of the maintainers in their responses. Issues closed by the maintainers without any reply or activity were discarded. Issues closed with unclear responses (e.g., "N/A", "thumbs_down") were also discarded since they did not provide clarity on the validation of the issue. We only considered the issues where there was some sort of discussion of the issue (e.g., "These todo’s shouldn’t be there, I agree ... but it’s not about defects/weaknesses here. It’s just a marker to include more operating systems in the future.") or a clear validation of the issue (e.g., "All false positives"). From the answers obtained, two of the co-authors manually inferred the classification of each warning. We use Cohen’s Kappa [10] to measure the inter-rater reliability of human decisions. Metrics. We measured Precision as described in Section 3.1.2.

3.2.3 Results. This section reports results. Issues. We reported a total of 1975 warnings in 228 issues (9 warnings per issue, on average). Project owners responded to 51 issues of the 228 issues we submitted, but only 33 issues were clearly discussed or validated—the equivalent to 298 warnings (Table 4). One issue for an "Empty Password" warning was fixed by one of the maintainers (82c3cb718); one tagged the issue with "waiting for contribution"; another commented asking to perform a pull request. Reply Evaluation. We used the following method to determine the warning classification (i.e., false or true positive) from the answers of project owners. We discarded warnings related to issues closed without any response or activity and issues that remained open or without any response by the time of our analysis. After that stage, two of this paper’s co-authors reviewed each of the answered issues. Each warning received two votes. Then, we ran a Cohen’s Kappa analysis to measure the inter-rater reliability of our choices to assess the confidence in our classification method. The kappa coefficient (k) shows the level of agreement between the two co-authors. The analysis yielded $k = 1.0$, i.e., a total agreement between both co-authors. Precision. Table 4 shows the number of true positives (TP) and the number of false positives (FP) per type of warning. In total, SLIC reported 83 true positives and 215 false positives for the 33 issues considered, which resulted in an average precision of 0.28 for SLIC. Note that the samples used for "Use of Weak Crypto. Algorithms", "Invalid IP Address Binding", "Empty Password" and "Admin by default" are relatively small, so results might not reflect the entire reality.

Summary: Results indicate that the precision of SLIC is even lower when evaluated by maintainers—developers with more

knowledge and context of the applications—of the software (drops to 28%). These results confirm our initial observations and indicate that better security IaC linters for Puppet are needed.

4 INFRASECURE: PUPPET SECURITY LINTER

The observations described in the previous section motivated the pursuit of a more precise security linter for Puppet scripts. The previous experiments ignited discussions with members of the development and security teams of PuppetLabs, as well as a project manager from Vox Pupuli. We leveraged the feedback obtained from the previous studies and the professional feedback to design a new security linter for the Puppet community, which we dubbed as INFRASECURE. More precisely, we created a new linter as a result of phase 1 (Figure 2) and incrementally evolved the linter according to the recommendations of professionals (Figure 2, phase 2), improving 7 rules of the SLIC ruleset and adding 3 new rules. The following sections report the new architecture (Section 4.1), design choices (Section 4.2) and security checkers (Section 4.3) that resulted from the feedback collection (Figure 2):

- **Phase 1**: Feedback from the owners of OSS projects, PuppetLabs and Voxpupuli Engineers (as described in Section 3) that led to the creation of INFRASECURE (v0.1.0);
- **Phase 2**: Two cycles of feedback from the Puppet and Prolific communities (as described in Section 5) that led to two new releases of INFRASECURE (v1.0.0 and v1.1.0);

4.1 Linter Architecture

One recommendation from the PuppetLabs team (phase 1) was to implement the set of the rules as plugins to the puppet-lint architecture\(^1\), through the puppet-lint check API\(^2\). This API facilitates the integration of new checkers in puppet-lint in addition, it allows the user to suppress warnings and disable or enable checkers—which are regarded as important features by the community. All security checks were developed as plugins to puppet-lint (Table 7). These checks are applied to the Abstract Syntax Tree (AST) of a Puppet manifest which is generated by an internal tokenizer\(^3\). INFRASECURE was implemented in Ruby and its CLI is available online\(^4\). The codebase of the linter is available at [https://github.com/TQRG/puppet-lint-infrasecure](https://github.com/TQRG/puppet-lint-infrasecure) and open to future contributions.

4.2 Design Choices

This section describes the design choices of our analysis, guided by the distinct cycles of feedback as described in Section 3 and Section 5; also, illustrated in Figure 2.

**Variable/Attribute Assignments (VASS).** From the preliminary analysis performed in Section 3, we have noticed security-related code smells being detected in logical conditions. For instance, `if has_key($userdata, 'env')` shows a logical condition that was incorrectly flagged as a hard-coded secret issue. Aiming to reduce the number of incorrect predictions, we implemented a rule to search for variable and attribute assignments in Puppet manifests—`isVarAssign(token)` and `isAttrAssign(token)` (cf. Table 7).

Reasoning about the token value (TOKVAL). Some of the rules did not reason about token.value. For hard-coded secrets, the linter only checks if the token value is not empty. While manually validating the samples used in our studies, we found false positives of hard-coded secrets. For instance, `aws_admin_username = downcase($::operatingsystem)` which does not store any actual secret. SLIC flagged this case as a hard-coded secret because the value assigned to the variable `aws_admin_username` is not empty. However, the rule needs to reason not only about the length of the right-hand side of the variable assignment but also about the type of token and value. INFRASECURE locates variable and attribute assignments in the AST and considers that secrets are usually stored in :STRING and :STRING tokens. In addition, we defined a database of known credentials (`isUserDefault(token.value)`)—credentials that are not considered secrets by the community\(^5\)—and, invalid secrets (`invalidSecret(token.value)`) which are consider as non-valid values for hard-coded secrets. The linter ignores all the credentials in this database. Feedback from distinct owners of OSS Projects is what drove us to make this decision is presented below:

**[User Default]**: “The names of these UNIX accounts are not considered to be secret. They are published openly as part of the PE documentation: [https://puppet.com/docs/pe/2019.8/what_gets_installed_and_where.html#user_and_group_accounts_installed](https://puppet.com/docs/pe/2019.8/what_gets_installed_and_where.html#user_and_group_accounts_installed)

**[Invalid Secret]**: “This are default users and default as found in every installed fpm package, there is most of the time a wwwrun or a www-data user depending on the system.”

Use of HTTP without TLS is fine sometimes (SAFE). As SLIC, INFRASECURE also flags every single occurrence of `http://`, i.e., it recommends to use TLS by default. For example, the tool flags `apturl => "http://deb.debian.org/debian"`, even though it refers to a credible source. Our definition of credible source is a source that can be trusted. However, different companies can have different opinions regarding the credibility of the same source. That is why this rule is customizable. We observed that this type of issues (CWE-319) are prevalent in Puppet files. Applications often use third-party libraries, which are usually configured in Puppet files, and the links to their sources are not necessarily unsafe. Also, depending on the context of an application, the configuration of localhost servers as HTTP may not be a problem. If no sensitive data is communicated, then there is probably no problem using http. INFRASECURE has a configuration file for safe domains, i.e., domains that are cleared to be use http. Thereby, infrastructure teams can customize their own configuration files. The feedback provided in Section 5 from two different practitioners, which supported this decision, is presented below:

**[WhiteList]**: “I think it is fine if localhost is used. Otherwise TLS should be mandatory. All the big financial organizations will not use this check because they cannot create internal certs or use letsencrypt.”

**[WhiteList]**: “By default, it’s unsafe to not use HTTPS. But for internal testing/development it is acceptable to me to not use HTTPS all the time.”

---

4. Gem is available at [https://rubygems.org/gems/puppet-lint-infrasecure](https://rubygems.org/gems/puppet-lint-infrasecure)

Hard-Coded Secret Division in different checkers (SECR).

In Section 3, we observed that the hard-coded secrets checker produces the most significant number of alerts. For instance, SLIC assumes a secret is a key, password or username. As mentioned previously in Section 2, the Common Weakness Enumeration list does not consider solo hard-coded usernames as a threat. Practitioners involved in our validation studies shared the same opinion. We analyzed the distribution of the different types of hard-coded secrets and realized that 48% of the secrets detected were usernames. Therefore, in the final version of our tool, we decided to separate the hard-coded secrets checker into three new checkers (one per type of secret). This way, developers can disable the username checker if they find it noisy. We did not delete the original checker; infrastructure teams can use it if they want to collect all the different types of secrets simultaneously. Feedback provided in Section 5 from a practitioner supported this decision:

"The main security issue is having the password hard-coded. About having the user hard-coded, it is possible to allow that as an initial setting that should be changed during the first configuration and, in that case, it is not so much a security issue."

4.3 Rules

INFRASECURE detects 12 different security smells in Puppet manifests. Table 5b presents the AST patterns that are searched in the AST for relevant nodes/sequences of nodes; and, table 5a presents the string patterns used to validate the information in those nodes. Table 7 shows the syntactic pattern matching rules per weakness which leverage the two sets of patterns mentioned before.

Hard-coded secrets (CWE-321, CWE-259, CWE-798): The top of the Table 7 contains 4 different rules for hard-coded secrets: one per secret; and a final one which detects all kinds of secrets at the same time (keys, password, and usernames). In addition to the design choices, the rules consider that secret values cannot be placeholders (isPlaceholder(), Table 5a).

Use of HTTP without TLS (CWE-319): One of the main findings of our analysis is that HTTP without TLS is not always problematic. Therefore, we created a configurable whitelist where infrastructure teams can add safe domains. The checker will not raise alerts when in the presence of a safe domain (isResource(), Table 7). INFRASECURE provides a default whitelist with known reliable sources such as http://deb.debian.org/debian. However, this default whitelist will be overwritten when the user configures a new one.

Suspicious Comments (CWE-546): This checker was controversial. It was recognized that it would be valuable to alert developers about comments in their code mentioning functionalities and weaknesses that might hint at attackers. However, keywords such as "todo", "later", and "later2" were considered noisy. We changed the list of keywords in response to the complaints and feedback obtained from the developers (isSuspiciousWord(), Table 5a).

Usage of Weak Crypto. Algorithms (CWE-326): INFRASECURE searches for in calls to functions (isFunctionCall(), Table 5b) implementing crypto algorithms such as "md5" and "sha1" in variable and attribute assignments (Table 7).

Table 5: INFRASECURE’s list of string and AST patterns.

(b) Patterns applied to the Abstract Syntax Tree (AST).

Invalid IP Address Binding (CWE-284): We found cases where the invalid IP 0.0.0.0 was in descriptions and commands. For instance, SLIC flags description => ‘Open up postgresql for access to sensu from 0.0.0.0/8’. IPs follow a dot-decimal notation, i.e., they should not include letters. INFRASECURE uses a less naive regex than the string pattern (isInvalidIPBind(), Table 5a).

Empty Password (CWE-258): Empty passwords are located the same way as hard-coded secrets, i.e., by focusing on variable and attribute assignments (Table 7). The rule isEmptyPassword() (Table 5a) verifies if the password is empty.

The strong_password https://rubygems.org/gems/strong_password ruby gem is used to determine if a password is strong or not.
we observed that the precision of SLIC was 64%. By implementing the two design choices mentioned before, we increased precision by 12 per cent points—when comparing SLIC’s precision in the proportional set (64%) with the precision of the first version of InfraSecure in the same dataset (76%), Table 6. As these changes were successful w.r.t. precision, we decided to implement the other improvements and conduct a new study with practitioners to collect more feedback about the tool and the anti-patterns covered.

5 PRACTITIONERS EVALUATION
InfraSecure was validated with practitioners experienced in security or configuration management technologies. We built an experiment to validate the warnings of the new tool. The experiment was shared with the Puppet communities on Slack (puppetcommunity.slack.com) and Reddit (r/puppet). We found 14 participants by this mean. Later, we leveraged Prolific[35][33] to gather more participants based on their experience and programming knowledge. In this experiment, a total of 339 warnings were validated by 131 practitioners. Furthermore, our improvements increased the precision of the tool from 28% to 83%. As illustrated in Figure 2, we ran two cycles of feedback collection and iteratively improve the tool with the feedback collected. This section describes 1) the methodology conducted with practitioners to validate the InfraSecure warnings; and 2) the results obtained from running the practitioners’ experiment.

5.1 Study Design
In this section, we detail how the validation study of InfraSecure was designed, and the population leveraged to conduct it. InfraSecure was improved based on the problems collected through the preliminary study and the validations with the maintainers of the software—which led to InfraSecure v0.1.0. To validate the new tool, we surveyed practitioners with experience in security, configuration management tools and programming knowledge by following recent recommendations to run studies on Prolific [33]. After the pre-screening, the practitioners were asked to validate and give feedback on 3 different warnings generated by InfraSecure.

Practitioners Recruitment. The participants were obtained using two distinct routes: 1) By sharing the study with online Puppet communities such as puppetcommunity.slack.com and Reddit (r/puppet); 2) By using the Prolific platform to gather practitioners with experience in security, configuration management tools and programming skills. Both communities integrate a considerable amount of members: slack has over 9k members, and Reddit has around 47k members. However, only 14 members participated in our study. Therefore, we used Prolific to collect more practitioners with experience in security and configuration management tools outside of these two communities. Prolific participants were monetarily compensated for answering each survey, while the participants collected in the communities were not.

Pre-Screening. Prolific is a platform where you can find participants to perform online research. As recommended in research on recruiting practitioners for user studies on prolific [33], we performed a pre-screening of the population to collect adequate participants for this study, i.e., participants with security and configuration management experience; and programming knowledge. Prolific has filters dedicated to the industry where the participants work or belong. We sent the pre-screening survey to prolific users working in the following industries: "Computer and Electronics, Software, System Administration, Software Development, System Integrators".
Then, we ordered those participants by priority where priority is the INFA-EXPERIENCE (CE) of years of experience in infrastructure/puppet. The goal of the study is to explain the study’s goal and ask the participant for her professional background. We obtained a total of 431 responses from different industries. Then, we ordered those participants by priority where priority is the count of experience in 1) at least one configuration management tool (CMEXP), 2) security (SECEXP), 3) infrastructure as a service (INFRAEXP), and 4) score in the programming questions (SCORE). Priority was calculated as follows: 0.3 * ((CMEXP + SECEXP + INFRAEXP)/3) + 0.7 * (SCORE/3) and varies between 0 to 3. A priority of 3 means the participant is adequate for the study, whereas a priority of 0 means the participant is not adequate. For the validation study, we only invited participants with priority equal to or greater than 1.5—which represented 53% of the initial responses (227 out of 431 participants).

`inWhitelist(t, value)` verifies if the URL is in the list of configurable safe domains/whitelist. If the URL is in the whitelist, an alert should not be raised. `isMalicious(t, value)` verifies if the software package version configured in the puppet script is in the database of malicious dependencies.

Manufacturing”, “Information Services and Data Processing”, “Product Development”, “Research laboratories”, “Scientific or Technical Services”, “Software”. The participants were asked to answer the following questions: 1) Do you have any kind of experience with configuration management tools? Choices: Puppet, Ansible, Terraform, Chef, Other; 2) Experience in Security (Number of Years); 3) Experience in Infrastructure as a Service (Number of Years); and three programming language questions about different puppet configurations. Due to space constraints, we do not present the questions here, but they are available in our replication package: study/practitioners/pre-screening/puppet-study-form.pdf.

We obtained a total of 431 responses from 8 different industries. Then, we ordered those participants by priority where priority is the count of experience in 1) at least one configuration management tool (CMEXP), 2) security (SECEXP), 3) infrastructure as a service (INFRAEXP), and 4) score in the programming questions (SCORE). Priority was calculated as follows: 0.3 * ((CMEXP + SECEXP + INFRAEXP)/3) + 0.7 * (SCORE/3) and varies between 0 to 3. A priority of 3 means the participant is adequate for the study, whereas a priority of 0 means the participant is not adequate. For the validation study, we only invited participants with priority equal to or greater than 1.5—which represented 53% of the initial responses (227 out of 431 participants).

**Validation Form.** We built a form online to share with the Puppet communities and practitioners. The initial page of the form explains the study’s goal and asks the participant for her professional background. Number of years of experience in security, and number of years of experience in infrastructure/puppet. The goal of the study is to validate the output of our new tool: INFRASECURE. Therefore, participants are required to validate 3 different warnings (one at each time). For each warning, the form presents a description of the issue and the piece of code where the issue is located (cf. Figure 4). Participants have to evaluate the issue and provide their validation: “Yes, I agree”, if the warning reports a security issue; “No, I disagree”, if it reports a false security issue; or, “I’m not sure”, when unsure. The participant can also provide additional feedback on the problem.

**Warnings Dataset.** For this experiment, we validated the output of 9 different rules (Table 7), where the warnings for weak passwords and malicious dependencies were mostly validated in the second round of feedback collection. We ran the INFRASECURE over a total of 1050 GitHub projects—collected from the dataset used in the preliminary study (Section 3). We created a uniform sample with 50 warnings per rule (i.e., a total of 450 warnings).

**Metrics.** We report the number of true positives (TPs), the number of false positives (FPs), the number of “Unsure” responses and precision—calculated as described in Section 3.1.2.

**5.2 Results**

We obtained a total of 131 participants: 74 in the first round of feedback; and 57 in the second round. Due to the lack of responses from participants, we were only able to validate 342 out of the 450 initial number of warnings. Table 8 shows the distribution of warnings and precision obtained for the final version of INFRASECURE (v1.1.0). At the end of this study, INFRASECURE reported a precision of 83%, where 54 of the warnings were False Positives.
### 5.3 Discussion & Limitations

This paper reports our approach to improve the ruleset of an IaC security iteratively linter in different cycles of feedback collection. However, the tool can still be improved with more sophisticated techniques such as data-flow analysis, which would fulfill the following feedback: *In puppet, pre-defining a password as empty does not mean it is empty (e.g., $ssl_password = " "). Many times these variables are changed later. Thus, for each empty password, InfraSecure verifies if the same variable was changed within the same file. If it was, then the linter will not raise an issue.*

In addition, some engineers suggested that usernames should only be reported as hard-coded secrets when paired with a password/key. For this, we must match the different pairs of credentials in a puppet manifest. To sum up, there are still opportunities to improve the precision and recall of InfraSecure. We reached out to owners of highly active GitHub projects that use Puppet reporting warnings detected by InfraSecure. Two owners mentioned that since the apps are not in production, they did not consider the issues relevant. Even after improving the linter to detect the anti-patterns correctly, some problems are still not problematic. This happens because the linter does not have context regarding the software’s usage, which will always be a source of False Positives.

In the future, we will continue to search for solutions to make the linter more context-aware since this is a known problem of linters.

### 6 ETHICAL STANDARDS AND COMPLIANCE

This section discusses compliance with the ACM Policy for Research Involving Humans,\(^2\) which ensures that the ethical and legal standards are met when research has human participants.

**Informed Consent.** One of the principles is to ensure that participants are informed about the fact that they are participating in a study. In our study, consent was collected differently for each experiment: for the first one, the research team agreed to participate in the study; for the OSS maintainers experiment, we used the puppet community slack to communicate and discuss the investigation with the maintainers; finally, for the practitioners’ experiment, we asked survey participants if they agreed to participate in our different surveys at the beginning of the pre-screening phase.

**Data Privacy.** For all experiments, we ensured that the participants’ private information was protected by not providing the participants’ personal data (e.g., GitHub usernames of the OSS maintainers, prolific participants’ names, ages, nationalities, etc.) in our replication package.

**Spam.** As mentioned in Section 3.2, we carefully organized the issues to minimize the amount of messages sent to maintainers [3, 27].

---

17]. Security smells of the same kind were all reported in a single GitHub issue. In addition, we designed the issues to be actionable by providing personalized fix suggestions and adding references that document the detected problems.

**Full Disclosure in Security.** Fully disclosing vulnerabilities on GitHub issues allows hackers to exploit unfixed vulnerabilities, creating risks for software users. Ideally, vulnerability disclosure should be performed confidentially. Yet, GitHub does not provide a feature to report them privately. Therefore, carefully performing full disclosure is accepted by OSS maintainers [2, 7]. Some OSS projects adopt security mailing lists. In those cases, disclosure should be performed through those mailing lists.

### 7 THREATS TO VALIDITY

This section presents potential threats to the validity of this study.

**Internal Validity:** As with any implementation, the scripts that we developed to run the tools and collect the metrics reported in the paper are potentially not bug-free. However, the scripts and outputs are open-source for other researchers and potential users to check the validity of the results.

**Construct Validity:** A potential threat is the manual analysis of the warnings raised by SLIC in the Puppet scripts, which can potentially be mislabeled. We tried to mitigate this by running a kappa analysis between the two co-authors. For the experiments with the OSS maintainers, we inferred the validations of the alerts from their comments. Although both co-authors inferred validations, and a kappa analysis was performed, we risk our inference being incorrect. It is also important to mention that even though we made an effort to collect feedback from experienced humans, their judgement can also not be 100% accurate, which can introduce error in the precision values reported.

**External Validity:** A potential threat to external validity is related to the fact that the set of Puppet scripts we have considered in this study may not accurately represent the whole set of vulnerabilities that can happen during development. We attempt to reduce the selection bias by gathering a large collection of real, openly available (hence, reproducible) Puppet scripts. Another potential threat is that we could have missed the latest updates to SLIC. To mitigate this risk, we contacted the authors of SLIC to confirm that the version available is true to the most recent one.

### 8 RELATED WORK

As IaC has become popular and prevalent, researchers have dedicated efforts to improve its quality. Jiang et al. conducted an empirical study on Puppet scripts to gain a deep understanding of the characteristics of such scripts and how they evolve over time [21]. Bent et al. investigated the quality and maintainability aspects of Puppet scripts [35]. Furthermore, Rahman et al. proposed prediction models (based on text mining) to classify defective IaC scripts [31]. Palma et al. created a catalog of software metrics for IaC scripts [11]. In addition, recent work has been developed to detect malicious packages published on registry maintainers such as npm and ruby gems [14]. Building and introducing linters earlier in the software development life-cycle shift security left and decreases the probability of shipping malicious packages.

There are several linters available for security but only the subject of this paper, SLIC, focuses in IaC scripts for Puppet [28]. The authors started by demonstrating the linter in the context of Puppet scripts, and later, the authors reproduced the same study for Chef and Ansible and created new tools for those technologies [30]. A major issue with linters is their lack of precision [9, 16, 23, 25, 27, 36]; low precision entails low reliability for developers. Previous research has shown the impact of this issue on the developers’ workflow and stressed it is essential to create precise tools; otherwise, the developers will not use them [4, 8, 12, 19, 22, 34]. As mentioned before, this study aims to gain a better understanding of the current capabilities of the only IaC security linter for Puppet and shed some light on how to move forward.

### 9 CONCLUSIONS & FUTURE WORK

In this study, we observed through a comprehensive study that security linters for IaC scripts still need to be improved to be adopted by the industry. This paper leverages community expertise to address the challenge of improving the precision of such linting tools. We focused on precision as it is critically important in this domain—false security warnings can be very disruptive. More precisely, we interviewed professional developers of Puppet scripts to collect their feedback on the root causes of imprecision of the state-of-the-art security linter for Puppet. From that feedback, we developed a linter adjusting 7 rules of an existing linter ruleset and adding 3 new rules. We conducted a new study with 131 professional developers, showing an increase in precision from 28% to 83%. Following the findings of a Google study [34], we show that authors of linters can improve their own tools if they focus on the users’ feedback. The takeaway messages of this paper are that (i) it is feasible to tune security linters to produce acceptable precision; and, that (ii) involving practitioners in discussions is an effective way to guide the improvement of those linters.

The observations that we made throughout this work pave the way for the following future work: extend INFRASECURE to detect other security vulnerabilities, integrate the tool with methods for automated patching, and port INFRASECURE to other configuration management tools.

**ACKNOWLEDGEMENTS**

We thank the Puppet Community for their support and involvement in the different studies.
